

II. CARBON AND CARBONATE ANALYSES, LEG 33

Donald H. Cameron, Scripps Institution of Oceanography, La Jolla, California

Leg 33 carbonate samples were collected onboard ship in 3-cc vials at the time the core was split open. On shore the samples were dried and ground to a homogeneous powder. The ground sediment was redried at 105°-110°C and two samples from each vial, a 0.1-g and a 0.5-g sample, were then weighted into LECO crucibles. The 0.5-g sample was acidified with dilute hydrochloric acid, washed with distilled water, redried, and analyzed for acid insoluble (organic) carbon using a LECO 70 carbon analyzer. The 0.1-g sample was treated only with distilled water to cake the sample before analysis for total carbon. If the result showed less than 10% CaCO₃, an additional 0.5-g sample was analyzed for greater accuracy. The calcium carbonate percentage was calculated as follows: (% total C - % organic C) × 8.33 = % CaCO₃. Although other carbonates may be present, all acid-soluble carbon was calculated as calcium carbonate. All results are given in weight percent.

Detailed descriptions of technique and theory are in Bader, Gerard, et al., 1970.

For control purposes a standard sediment was made up from Deep Sea Drilling material and analyzed for total carbon at predetermined intervals with regular samples. Listed below are the statistical data for this standard.

DSDP Std.	No. of Samples	Total Carbon as % CaCO ₃	Standard Deviation	Maximum Range
2	53	80.7	0.8%	4.0%

These data indicate the precision of the mechanical aspect of the LECO analysis and do not necessarily reflect the precision of the total analytical procedure, which may be affected by factors such as inhomogeneous standard or contamination during sample preparation.
