

10. CHEMICAL ANALYSES OF INTERLABORATORY STANDARDS

T.L. Wright, U.S. Geological Survey, Reston, Virginia

Four samples of basalt from Holes 332A and 332B were designated as standards to be analyzed by all investigators working on chemistry of Leg 37 basalts. In addition, wet chemical analyses of each standard were obtained from the U.S. Geological Survey's Denver rock analysis laboratory and from the U.S. National Museum. The analyses for major elements reported by all investigators are shown in Table 1.

For purposes of comparison each analysis was corrected for CO₂ and normalized to dry weight. Standards 1, 2, and 3 were corrected by calculating CO₂ as calcite and adjusting CaO accordingly. Standard 4 contains iron and magnesian carbonates and was corrected for a mixed carbonate consisting of 91% MgCO₃ and 9% FeCO₃. After normalization ferric iron was converted

to ferrous and all iron was expressed as "FeO." Where two iron values and/or CO₂ were not reported, an average value for Fe₂O₃ and CO₂ was assigned based on values given by the other laboratories. All adjusted and recalculated analyses are shown in Table 2.

The interlaboratory agreement is good in general although small but consistent differences are apparent when comparing the results of any two laboratories for the four standards. Analyses of Standards 1-3 are plotted on MgO variation diagrams in Figure 1. The total range of interlaboratory variation exceeds in some cases the variation found within single lithologic units analyzed on shipboard. This makes it difficult to make consistent chemical classifications when using analyses from different laboratories.

TABLE I
Analyses of Interlaboratory Standards

	USGS	USNM	BREST	DAL	USSR	URI	WOODS	R-UB	IMP
Standard 1: Sample 332A-8-2, 2-15 cm
