23. APTIAN TO CENOMANIAN DINOFLAGELLATE CYSTS FROM THE MAZAGAN PLATEAU, NORTHWEST AFRICA (SITES 545 AND 547, DEEP SEA DRILLING PROJECT LEG 79)¹

Raimond Below, Institut für Paläontologie, Universität Bonn²

ABSTRACT

Eighty-eight samples of Aptian to lower Cenomanian sediments of Sites 545 and 547, DSDP Leg 79, from the Mazagan Plateau area (offshore Northwest Africa) were analyzed for palynomorphs. The very rich dinoflagellate cyst assemblages make it possible to narrow shipboard age determinations and to correlate Sites 545 and 547. The distribution of 174 dinoflagellate cyst taxa is tabulated in this study and the biostratigraphic value of selected dinoflagellate cysts is discussed. Additional taxonomic remarks are made about some species. The new dinoflagellate cyst species Aptea almohadensis, Occisucysta hinzii, O. mazaganensis, and the subspecies Maghrebinia perforata (Clarke and Verdier, 1967) Below, 1981 ssp. mirabilis are described.

INTRODUCTION

Sites 544 to 547 were drilled in the Mazagan Plateau area of the Moroccan Atlantic continental slope during DSDP Leg 79. Of these, Sites 545 and 547 were chosen for biostratigraphic analysis of mid-Cretaceous dinoflagellate cyst assemblages.

Site 545, at the northwestern foot of the Mazagan Plateau slope, consists of 701 m of Jurassic to Quaternary sediment. For this palynological study, 278 m of green, carbonaceous claystone with a few meters of dolomitized chalk at the base are of interest. The age was determined by shipboard scientists as early late Aptian to middle or late Cenomanian. These strata rest unconformably on Jurassic carbonates and are separated by a further unconformity from the overlying Neogene chalks.

Site 547, 14 km north-northeast of Site 545, is situated on the northeastern slope of a basement horst. Holes 547A and 547B penetrate a total of 1030 m of Jurassic to Quaternary sediment. The samples for this study were taken from a 351-m-thick section of Albian to Cenomanian carbonaceous clay- and mudstones. This interval is separated from the underlying Jurassic limestones by a major hiatus, and from overlying debris flows, reworked during the Late Cretaceous and Paleocene, by an unconformity.

A total of 88 samples were prepared using common palynological techniques. In addition to various palynomorphs such as pollen and spores, acritarchs, scolecodonts, phycomycetes, "micro-foraminifers", wood fragments, and cuticula, all samples yielded rich dinoflagellate cyst assemblages, with many individuals and often very high species diversity. Preservation of the cysts is very good, except for a few reworked specimens.

Analysis of these dinoflagellate cyst assemblages has made possible the detailed determination of sediment ages, subdivision of the mid-Cretaceous sequence, and correlation of Site 547 with Site 545. The results will be discussed in the biostratigraphic section of this chapter. Another section deals with dinoflagellate cyst taxonomy; it includes short remarks about selected species and descriptions of four new taxa.

BIOSTRATIGRAPHY

Because reliable, detailed, and universally valid dinoflagellate cyst zones for the mid-Cretaceous Period are not yet formalized, age determination is based on comparison with dinoflagellate cyst assemblages known from the neighboring, stratigraphically well-dated sections of Site 370 (Williams, 1978) and Moroccan onshore sections (Below, 1981; Below, 1982a, 1982b).

Site 545 (33°39.86'N; 9°21.88'W; water depth 3142 m)

A total of 278 m of mid-Cretaceous sediment was drilled, extending from Core 56 to Core 27. The basal 10 m consist of yellow grey dolomitic chalks resting immediately upon the Jurassic/mid-Cretaceous unconformity. These strata were dated as early late Aptian by shipboard paleontologists (shore-based study). The series continues with a monotonous interval of carbonaceous claystones with a few layers of clay pebbles in Cores 40, 35, and 34. Within this sequence, the following shipboard age determinations were proposed, using foraminifers and nannofossils: Core 56, early Aptian (?late Barremian); Cores 55 to 44, late Aptian; Cores 44 to 37, late Albian, with problematic existence of early Albian equivalents; Cores 36 to 34, early(?) Cenomanian; Cores 34 to 33, middle(?) Cenomanian; Cores 33 to 27, late Cenomanian. These ages have subsequently been further refined with shore-based study (see chapters by Leckie and Wiegand, this volume). The mid-Cretaceous/Neogene unconformity is located within Core 27.

Analysis

From Hole 545, 39 samples were collected: 3 in 11 m of the ?Barremian-Aptian sequence: 18 in 110 m of upper Aptian sediments; 12 in 70 m of the upper Albian interval, and 6 in 87 m of Cenomanian age. The distri-

Figure 1. Distribution of dinoflagellate cysts in the mid-Cretaceous of Hole 545.

bution of the 160 taxa recorded within these samples is shown in Figure 1.

Many species are present throughout the whole Aptian to Cenomanian sequence. There are also a number of longer-ranging dinoflagellate cysts. Many of these taxa dominate in most assemblages, having more than 100 specimens: for example, *Cyclonephelium brevispinatum*, *Florentinia radiculata*, *F. mantellii, Gonyaulacysta heli*- coidea, Odontochitina operculata, Oligosphaeridium complex, O. irregulare, Spiniferites ancoriferus ssp. ancoriferus. Other species show maximum frequency in limited intervals, which can be of stratigraphic value: Aptea eisenackii, Pervosphaeridium truncatum, and Trichodinium castanea. Some species, in contrast, are found to dominate only during a very short stratigraphic interval: Aptea almohadensis, Chlamydophorella discreta, Cri-

Figure 1. (Continued).

broperidinium orthoceras, Cyclonephelium maugaad, Kiokansium corollum, K. hydra, Systematophora cretacea. Litosphaeridium siphoniphorum. The distribution of other short-ranging cyst species tends gradually to increase or decrease over their stratigraphic interval: Maghrebinia perforata ssp. mirabilis, Oligosphaeridium verrucosum, Oodnadattia alata, Subtilisphaera deformans. Most of the remaining species are short ranging to very short ranging and have variable frequency. There are only a few samples where there is no base or top range for at least one or more taxa. This allows a very detailed sequencing of Site 545. However, such a division, based on local dinoflagellate cyst ranges, has no universal validity. Many such local guide-fossils are absent in equivalent time periods in neighboring sections,

Figure 1. (Continued).

for example, Site 547 (this chapter), Site 370 (Williams, 1978), and onshore sections (Below, 1981; Below, 1982a, 1982b). Only selected samples were examined, although, in contrast to various published studies of dinoflagellate cyst assemblages, they were taken at very short intervals. Nevertheless, it is probable that many occurrences of "short-ranging" species in strata between sample points were by chance not found. Only continuous trench sampling would document all faunal horizons.

With this in mind, this chapter discusses only selected cysts, not all 160 taxa occurring at Site 545. For more detailed information about other species, the reader is referred to the dinoflagellate cyst distribution chart, Figures 1 and 2.

The few individuals from a poor dinoflagellate cyst assemblage in Sample 545-56-6, 55-57 cm give little evidence for age determination. The four species, *Oligosphaeridium complex*, *O. totum* ssp. *minor*, *Spiniferites*

Figure 1. (Continued).

ramosus ssp. ramosus, and Tanyosphaeridium boletum, are all long-ranging taxa, known from Lower and Upper Cretaceous sediments. This sample and Sample 545-56-3, 58-60 cm were taken from a sequence of crushed and faulted green claystone, dated as (?Barremian) Aptian by the shipboard party (subsequently dated as early late Aptian by foraminifers; Leckie, this volume). Because of the stratigraphically insignificant dinoflagellate cyst association this age determination can neither be verified nor rejected for Sample 545-56-6, 55-57 cm. However, an Aptian—even an early Aptian age—can be proposed for Sample 545-56-3, 58-60 cm, because characteristic dinoflagellate cyst populations found in middle Aptian sediments of Moroccan onshore sections do not occur below Core 53. The population of Sample 545-56-3, 58-60 cm comprises 21 species, of which three are of stratigraphic interest: *Aptea eisenackii* (peak), *Occisucysta tenuiceras*, and *Cerbia tabulata*. Both of the form-

Figure 2. Stratigraphic ranges of selected dinoflagellate cysts in Hole 545, between Cores 30 and 56. X = dinoflagellate cyst taxa also present in the Albian (Alb) and/or Cenomanian (C) of Holes 547A and 547B.

er are limited to the Aptian of the onshore Ida ou Tanane section (Below, 1981), whereas *Cerbia tabulata* shows equal frequency in the Barremian and Aptian of this onshore locality. Species with base ranges in this sample and maxima during the Aptian are *Cribroperidinium orthoceras*, *Cyclonephelium maugaad*, and *Kiokansium hydra*. The base range of *Florentinia radiculata* corresponds to its first occurrence in the Aptian of Site 370 (Williams, 1978).

Sample 545-55-6, 71-73 cm yielded a very rich population, both in species diversity and number of individuals. Of 48 dinoflagellate species, 38 have their site-specific base ranges in this sample. Sample 545-55-6, 71-73 cm contains dinoflagellate cysts that are regarded as typical of Aptian and/or younger sediments, such as Achomosphaera verdieri, Aptea eisenackii, A. polymorpha. C. maugaad, F. radiculata, O. sousensis, O. tenuiceras, and Prolixosphaeridium parvispinum. Most of these species are very abundant in this sample and thus clearly correspond to their known peak in the Aptian. Williams (1978) has demonstrated that the characteristic P. parvispinum (as P. granulosum) has its base range within Aptian sediments at Site 370. Cribroperidinium orthoceras, K. hydra, and Rhynchodiniopsis aptiana, which also occur in Sample 545-55-6, 71-73 cm, are typical of both Barremian and Aptian ages.

Danea chibanis, in Sample 545-54-3, 43-47 cm, is well known in the middle Aptian of Moroccan onshore sections (Below, 1981). Protoellipsodinium touile ssp. touile in Sample 545-53-3, 90-94 cm and P. seghire ssp. seghire in Sample 545-52-2, 123-126 cm strengthen the impression that these are all middle Aptian dinoflagellate cyst populations. This last sample also yields the first appearance of the morphologically very characteristic and short-ranging Oligosphaeridium verrucosum.

Only a few species are introduced as new components in the dinoflagellate cyst associations in the interval between Samples 545-51-6, 66-69 cm and 545-50-1, 147-150 cm. Of these, *Hapsocysta peridyctia* and *Systematophora* sp. MAZ may in the future prove to be of stratigraphic value for middle Aptian time. In this sample interval, low species diversity is correlated with the absence of dominant species with high numbers of specimens.

This is obviously different in Sample 545-49-5, 49-52 cm, which shows high species diversity and great numbers of dinoflagellate cyst individuals. Eleven species occur in this sample for the first time. Of these, *Aptea almohadensis, Chlamydophorella nyei, Coronifera tubulosa*, and *Subtilisphaera deformans* immediately become dominant species, but only for a short period. It is in this sample that *Cassiculosphaeridia tazadensis* has its greatest frequency; this is a significant dinoflagellate cyst from the middle Aptian in the Ida ou Tanane onshore section (Below, 1981). Morphologically characteristic species with base ranges are *Carpodinium granulatum* and *Occisucysta hinzii*.

Many species are new in the dinoflagellate cyst assemblages between Samples 545-48-6, 16-18 cm and 545-44-2, 78-82 cm. Some of these are unknown in the Moroccan lower and middle Aptian: *Codoniella campanu*-

la, C. psygma, Kleithriasphaeridium? sarmentum, Nematosphaeropsis? singularis, and O. cf. tenuiceras. Since they are associated with dinoflagellate cyst populations in which typical Aptian species dominate, it is possible that they may indicate a late Aptian age for this stratigraphic interval. This is supported by the many Hystrichosphaerina schindewolfii specimens in Sample 545-46-4, 63-66 cm. Their presence makes it possible to connect this sample with the Systematophora schindewolfii Zone of the late Aptian (Williams, 1975, 1978). Other species, such as Ellipsoidictyum imperfectum, Oligosphaeridium indicum, and S. cretacea, which have base ranges in the sequence between Samples 545-47-6, 72-75 cm and 545-46-2, 63-66 cm, do not occur in the Moroccan material before the Albian. Some species typical for the Barremian-Aptian have their top ranges within the interval between Samples 545-46-2, 63-66 cm and 545-41-4, 0-4 cm: Cassiculosphaeridia tazadensis, Cerbia aucda, C. tabulata, Occisucysta tentoria, and Spiniferites magnoserratus. Species of the genus Cerbia seem to be good guide fossils, for they never extend above the Aptian/Albian boundary (Williams, pers. comm., 1981). Nevertheless, stratigraphically reliable species indicate that the Aptian extends as high as Sample 545-40-6, 57-60 cm. Species having their top range within this sample and the somewhat older Sample 545-41-1, 47-49 cm are Cassiculosphaeridia reticulata, Cribroperidinium orthoceras, Cyclonephelium maugaad, K. eoinodes, Meiourogonyaulax stoveri, O. sousensis, Protoellipsodinium seghire ssp. seghire, Pterodinium aliferum, and Rhynchodiniopsis aptiana.

Several thin beds of claystone conglomerates have been recorded within Core 40. Shipboard scientists proposed a very minor hiatus. Changes in the composition of dinoflagellate cyst populations demonstrate it to be a major hiatus. Sample 545-40-6, 57-60 cm, 80 cm below the first pebble conglomerate, is of Aptian age, whereas Sample 545-40-2, 116-119 cm yields dinoflagellate cysts typical for the very late Albian. Most species which have base ranges from Sample 545-40-2, 116-119 cm to Sample 545-31-1, 130-133 cm characterize the Albian/Cenomanian boundary. No dinoflagellates significant for the lower or middle Albian from onshore sections were recognized. Cyclonephelium chabaca, Litosphaeridium siphoniphorum, Maghrebinia chleuh, M. perforata ssp. mirabilis, M. perforata ssp. perforata, and Palaeohystrichophora infusorioides occur within the Ida ou Tanane onshore section in the highest Vraconian and are known to range into the Cenomanian (Below, 1981).

There are problems in determining the exact position of the Albian/Cenomanian boundary at Site 545 (see also discussion of Site 547, later). Sample 545-39-1, 93-96 cm contains the species *P. infusorioides*, the base range of which, according to Williams (1978), marks the beginning of the Cenomanian at Site 370. This is in agreement with the work of Clarke and Verdier (1967), who erected the *Hystrichosphaeridium siphoniphorum* Zone of Cenomanian to ?Turonian age with three subzones. The base of this zone and its basal subzone, respectively, are marked by the first appearance of *P. infusorioides*. Palynologically, this can be taken as the base of the Cenomanian (Clarke and Verdier, 1967). Nevertheless, *Florentinia berran, F. resex, Maghrebinia chleuh, M. perforata* ssp. *perforata*, and *Oodnadattia alata*, well known in upper Albian onshore sections (Below, 1981; Below, 1982b), occur within Site 545 with base ranges that are younger than the first appearance of *P. infusorioides*. A comparison of dinoflagellate cyst assemblages from well-dated onshore sections with those from Site 545 seems to indicate that *Xenascus ceratioides* is, at least regionally, a more reliable marker for the beginning of the Cenomanian; therefore, it is used here to establish the Albian/Cenomanian boundary between Samples 545-38-1, 120-123 cm and 545-37-2, 84-87 cm.

According to Williams (1978), the abundant *Epelidosphaeridia spinosa* in Sample 545-30-1, 130-133 cm demonstrate that this stratum is not younger than earliest Cenomanian. The sequence between the first occurrence of *E. spinosa* and Sample 545-37-2, 84-87 cm, which contains the base range of *X. ceratioides*, would, therefore, be of basal Cenomanian age (Williams's term). This conclusion would be supported by the presence of *Kiokansium corollum*, whose range, according to Williams (1978, as *Cleistosphaeridium polypes* ssp. A), should not extend over the *basal/early* Cenomanian boundary.

Site 547 (Holes 547A and 547B) (33°46.84'N; 09°20.98'W; water depth 3938 m)

A total of 351 m of mid-Cretaceous sediment were cored in Hole 547A between Cores 39 and 73 and in the reentry Hole 547B between Cores 1 and 7. The sequence between Cores 547B-6 and 547A-39 consists of grayish green claystone and mudstone with common, intraformational flat-pebble mudstone conglomerate layers. It was dated by shipboard paleontologists as ranging from the late Albian to middle Cenomanian. It rests with a hiatus on Upper Jurassic to Lower Cretaceous nodular limestone and terminal claystone. The top of the mid-Cretaceous section is marked by an unconformity upon which Upper Cretaceous and Lower Tertiary strata were recorded.

Within the sequence studied here, age determinations proposed in the shipboard report using nannofossils were: 547A-39-1, 140 cm to 547A-40,CC, middle and late Albian to middle Turonian; 545A-41,CC to 545A-62,CC, early Cenomanian to early Turonian; 547A-63,CC through 547B-6-1, 107 cm, late Albian. Ages using foraminifers were: Cores 547A-39 to 547A-46, late Cenomanian; 547A-47 to 547A-62, early Cenomanian; 547A-63 through 547B6-1, 107 cm, late Albian. Redeposition within the section masks clearly defined boundaries.

Analysis, Hole 547B

Thirteen core samples were collected from a 48-m upper Albian interval in Hole 547B (with high sample density, e.g., 10 samples from 9.5 m of Core 5). Ninety taxa were recorded in Hole 547B; their distribution is shown in Figures 3 and 5.

All 10 samples of Core 547B-5 yielded rich dinoflagellate cyst populations. Dominant species are Cyclonephelium brevispinatum, Litosphaeridium conispinum, Odontochitina operculata, Oligosphaeridium complex,

Figure 3. Distribution of dinoflagellate cysts in the late Albian of Hole 547B.

Pervosphaeridium truncatum, and Spiniferites multibrevis ssp. seghiris. Important components are Chlamydophorella nyei, Coronifera oceanica, Exochosphaeridium phragmites, Florentinia mantellii, Gonyaulacysta helicoidea, Kiokansium corollum, Maghrebinia perforata ssp. mirabilis, O. irregulare, P. pseudohystrichodinium, S. ancoriferus ssp. ancoriferus, and S. cf. wetzelii. In comparison with dinoflagellate cysts from biostratigraphically well dated onshore sections, the association L. siphoniphorum, M. chleuh, M. perforata ssp. mirabilis, and M. perforata ssp. perforata characterize earliest Cenomanian and/or late Albian. This is supported by the presence of F. berran and F. resex in the somewhat younger Core 547B-2. However, the late Albian age is more probable and is proposed here, because Xenascus ceratioides, with a base range at the beginning of the Cenomanian (see later discussion) is absent in Hole 547B. It appears for the first time in Core 547A-69.

It is difficult to correlate Core 547B-5 with the sequence of Hole 547A. Theoretically, such correlation should be easy by comparing the distinctive base ranges of the species named earlier in Hole 545 with their base ranges in the continuous strata of Hole 547A, which are clear. However, these species all make their first appearance within the deepest sample in Hole 547B, Sample 547B-5-7, 40-43 cm. This first record does not of course imply that the sample is their biostratigraphic base range.

Some characteristic Aptian taxa are recorded in Hole 547B samples: Callaiosphaeridium trycherium, Cassiculosphaeridia reticulata, Muderongia perforata, Occisucysta sousensis, and Systematophora silyba. These are almost all single specimens, a fact that indicates reworking of older sediments.

Analysis, Hole 547A

Eleven core samples were collected from an 85-m upper Albian interval in Hole 547A, and 25 samples from a 236-m Cenomanian section. An additional sample, 547A-21-4, 110-113 cm, from a conglomerate layer within Eocene sediment, was analyzed for palynomorphs. In Hole 547A 91 taxa were recorded; their distribution is shown in Figures 4 and 5.

Cores 547A-72 and 547A-73 overlap with Cores 547B-1 to 547B-3, and the dominant species in the dinoflagellate cyst assemblages of both core intervals correspond. The dinoflagellate cyst populations of nearly all samples collected from Hole 547A are characteristic of the Albian/Cenomanian boundary section (see earlier discussion). If one assumes that the base range of *Xenascus ceratioides* begins with the Cenomanian, then the interval from Samples 547A-73-1, 148–150 cm to 547A-70-2, 70-93 cm, where *X. ceratioides* is absent, can be dated as Albian, whereas the first record of this species in Sample 547A-69-2, 108–110 cm implies that the sample is Cenomanian.

The section from Sample 547A-69-2, 108-110 cm to Sample 547A-44-2, 0-2 cm belongs to the Cenomanian *Cleistosphaeridium polypes* Assemblage Zone of Williams (1975), erected on the basis of dinoflagellate cyst material from Scotian shelf sections. Besides other species listed by Williams, *Kiokansium corollum* (= C. polypes sp. A sensu Williams, 1978) does not range into

Figure 4. Distribution of dinoflagellate cysts in the Albian/Cenomanian of Hole 547A.

the Turonian. Therefore samples up to 547A-44-2, 0-2 cm all with K. corollum, are certainly no younger than Cenomanian. According to Williams's study of dino-flaglellate cysts from Site 370 (Williams, 1978), K. corollum does not even extend into the early Cenomanian and is restricted to the base of the Cenomanian. However, detailed comparison between the data of Williams and those elaborated for Site 547 must be made very critically. Some of Williams key taxa with time-diagnostic base and top ranges, not occurring together within one population at Site 370, are associated in a single sample from Hole 547A (examples are Florentinia radiculata and F. stellata, or K. corollum and X. cerati-

oides). If we accept that the latest occurrence of K. corollum is at the base of the Cenomanian, the whole sequence from Sample 547A-69-2, 108-110 cm to Sample 547A-44-2, 0-2 cm must be dated as earliest Cenomanian. This proposal is perhaps strengthened by the absence of *Epelidosphaeridia spinosa*, which begins, according to Williams (1978), in the early Cenomanian, and which was used earlier in this chapter to establish the basal/early Cenomanian boundary in Hole 545. There are similar difficulties in making comparisons with the zonation of Clarke and Verdier (1967). Their data show, for example, that *Dinopterygium perforata* (= Maghrebinia perforata ssp. perforata), with a top

Figure 4. (Continued).

range at the upper limit of the *D. perforata* Subzone, and *X. ceratioides*, the base range of which marks the beginning of the superjacent *Palaeoperidinium spinosum* Subzone, are never found together. However, these fossils are found in association in many populations over a long interval in Hole 547A. It is, therefore, only possible to correlate this section, from 547A-69-2, 108-110 cm to 547A-44-2, 0-2 cm with the *Hystrichosphaeridium siphoniphorum* Zone of Clarke and Verdier (1967), which comprises these two subzones. Nevertheless, a more detailed local correlation of Holes 547A and 547B is possible with some characteristic short-ranging dinoflagellate cyst species, as is demonstrated in the range chart of selected dinoflagellate cyst taxa (Fig. 5).

The unit from 225 to 269 m of Hole 547A consists of conglomerate beds containing clasts reworked from older formations and resedimented during the Eocene. One of these clasts, Sample 547A-21-4, 110-113 cm, was analyzed for palynomorphs. The assemblage of *F. resex, F. stellata, K. corollum, Litosphaeridium siphoniphorum, Maghrebinia perforata* ssp. *perforata, Oodnadattia alata,* and *X. ceratioides* is comparable to the dinoflagel-

Figure 5. Stratigraphic ranges of selected dinoflagellate cysts in Hole 547A, between Cores 37 and 73 and Hole 547B, between Cores 1 and 5. X = dinoflagellate cyst taxa also present in the Aptian (Apt), Albian (Alb), and Cenomanian (C) of Hole 545.

late cyst populations found in the interval from Sample 547A-69-2, 108–110 cm to 547A-44-2, 0–2 cm, and the clast is therefore dated as earliest Cenomanian.

CONCLUSIONS

To summarize the results of this biostratigraphic chapter, age determinations based on dinoflagellate cyst analysis are, for Holes 547,547A, and 547B:

545-32-1, 29-33 cm to 545-31-1, 130-133 cm: early Cenomanian 545-37-2, 84-87 cm to 545-33-1, 90-94 cm: earliest Cenomanian 545-40-2, 116-119 cm to 545-38-1, 120-123 cm: late Albian 545-48-6, 16-18 cm to 545-40-6, 57-60 cm: late Aptian 545-53-3, 90-94 cm to 545-49-1, 34-37 cm: middle Aptian 545-56-6, 55-57 cm to 545-54-3, 43-47 cm: early (?) Aptian

547A-69-2, 108-110 cm to 547A-44-2, 0-2 cm: earliest Cenomanian

547A-73-1, 148-150 cm to 547A-70-2, 90-93 cm: late Albian

547B-5-7, 40-43 cm to 547B-2-2, 0-2 cm: late Albian

Sites 545 and 547 are correlated by comparing the Albian/Cenomanian boundary, marked by the base range of X. ceratioides at the beginning of the Cenomanian. Core 545-37 is comparable to Core 547A-69, since both cores include this boundary.

ADDENDUM

At the postcruise meeting for Leg 79 it was decided that 18 additional samples of Hole 547B should be analyzed for dinoflagellate cysts. These samples are:

547B-6-2, 6-7 cm; 547B-6-3, 57-58 cm; 547B-6-4, 76-77 cm; 547B-7-4, 54-56 cm; 547B-7-3, 124-126 cm; 547B-7-3, 94-96 cm; 547B-7-2, 133-135 cm; 547B-7-1, 42-43 cm; 547B-8-3, 26-27 cm; 547B-8-2, 118-120 cm; 547B-8-1, 89-91 cm; 547B-10-4, 50-51 cm; 547B-10-3, 9-10 cm; 547B-10-2, 125-126 cm; 547B-11-4, 80-81 cm; 547B-11-3, 3-4 cm; 547B-11-2, 138-139 cm; 547B-11-1, 139-140 cm. The samples were taken from limestones with clay interbeds located immediately below the section studied in this chapter and dated by shipboard paleontologists as Early Cretaceous to Middle Jurassic. All these samples were palynologically barren.

TAXONOMY

This section is divided into two parts. The first lists names of all dinoflagellate cyst taxa encountered during this study, arranged in alphabetical order of genus names, with references to plate and figure numbers where applicable; numbers in parentheses refer to the position of the species in the distribution charts for Holes 545, 547B, and 547A (Fig. 1, 3, and 4, respectively). A zero indicates that the species is absent from that particular hole. Species marked with an asterisk are discussed in more detail in the second part, which provides morphologic descriptions or systematic classifications.

Illustrated specimens are housed in the micropaleontological collection of the Institut für Paläontologie, Rheinische Friedrich-Wilhelms Universität Bonn, Germany.

Dinoflagellate Cyst Taxa

- Achomosphaera neptuni (Eisenack, 1958) Davey and Williams, 1966. (58-0-0)

Description of Selected Dinoflagellate Cyst Taxa

Class DINOPHYCEAE Fritsch, 1929 Order PERIDINIALES Haeckel, 1894

Genus APTEA Eisenack 1958, emend. Davey and Verdier, 1974 Junior synonyms. Aptea Eisenack, 1958, emend. Dörhöfer and

Davies, 1980; Doidyx Sarjeant, 1966.

Type species. Aptea polymorpha Eisenack, 1958.

Diagnosis. Eisenack, 1958, p. 393; Davey and Verdier, 1974, p. 640.

Aptea almohadensis n.sp.

(Plate 1, Figs. 5, 6, 7)

Derivatio nominis. After the dynasty of the Almohavids, kings of the Maghreb in the eleventh century.

Diagnosis. Proximate, lenticular cyst, shape subsphaeroidal to asymmetrical; with a left antapical bulge and occasionally with a right lateral bulge in the region of the postcingular paraplate girdle. Apex rounded or with a narrow bulge. Paratabulation presumably ceratiacean—not completely indicated: 1'-4', 1''-6''' as, Xc, X''', Xs, X''''. Archeopyle apical, with simple, free, asymmetrical operculum, type $\overline{4}$ A_{1'-4'}. Autophragma of varying thickness, very finely reticulated, rarely smooth. Cyst ornamentation very sparse and in most cases without rules of orientation. Ornaments as low, solid, flattened, interconnected ledges, isolated short spines with distally acuminated or blunted ends, or simple cones forming tubercles. Sometimes these ornaments are arranged to pandasutural lines.

Holotype. Slide II-6946: 49.6/100.1

Type locality. Leg 79, Sample 545-49-5, 49-52 cm.

Dimensions. Holotype length (without apical calotte) 58 μ m, breadth 60 μ m, maximal height of ornaments 2 μ m; other specimens: length 50-60 μ m, breadth 60-75 μ m, maximal height of ornaments 1-4 μ m.

Description. The cyst shape is highly variable because of the development of an apical, right lateral and an asymmetrically arranged antapical bulge. Specimens with an asymmetrical shape caused by the presence of a left antapical bulge and therefore typical of the genus *Aptea* are present, as well as cysts with a subsphaeroidal or sphaeroidal outline typical of the genus *Cyclonephelium*. The additional development of a right lateral bulge shows the close connection of these specimens to individuals of the genus *Pseudoceratium*. Reconstruction of

paratabulation is only indirectly possible for the epicyst by studying the archeopyle suture and breakages of opercula and archeopyle margin. There are four apical paraplates. 1' and 2' are compact and polygonal, whereas 3' and 4' are typically elongated and thus cause the very asymmetrical operculum shape. The precingular paraplate series is divided into six precingulars and the plate as. Paratabulation of the hypocyst is unknown. The sparse distribution of low ornaments such as spines or tubercles makes any consideration of penitabular alignment along parasutures impossible. Because of this pandasutural zones are also not developed. In few cases, ornamentation is absent.

Comparison. This new species is related to *Aptea eisenackii* (Davey, 1969) Davey and Verdier, 1974. The sparse cyst ornamentation characteristic of *A. almohadensis* is a result of the strong reduction of ornaments in *A. eisenackii*.

Occurrence. See Figure 1, No. 96: Sample 545-49-5, 49-52 cm to Sample 545-47-2, 97-99 cm; middle to late Aptian.

Genus DISSILIODINIUM Drugg, 1978

Type species. Dissiliodinium globulum Drugg, 1978. Diagnosis. Drugg, 1978, p. 45.

Dissiliodinium globulum Drugg, 1978

(Plate 3, Figs. 9, 10, 11)

Remarks. Research results of archeopyle type and epicystal paraplate patterns compiled by Below (1981) are verified by the rich DSDP material. Nevertheless, a few remarks about the existence of special apical structures that can be interpreted as reflections of preapical plates of motile dinoflagellate theca must be added. The structure, a small, smooth apical area, is somewhat raised against the surrounding cyst wall. In other cases, boundaries are marked as faint lines that result from a fusion of the small granulae of the cyst wall. This interesting structure, interpretated as reflections of 1PR and 2PR, is illustrated in Plate 3, Fig. 10.

Occurrence. See Figure 1, No. 11: Sample 545-56-3, 58-60 cm to Sample 545-41-4, 0-4 cm, Aptian; Figure 3, No. 49: Sample 547B-5-5, 100-103 cm to Sample 547B-4-3, 21-24 cm; late Albian.

Genus HYSTRICHOSPHAERIDIUM Deflandre, 1937, emend. Davey and Williams, 1966

Type species. Hystrichosphaeridium tubiferum (Ehrenberg, 1838) Deflandre, 1937, emend. Davey and Williams, 1966.

Diagnosis. Deflandre, 1937, p. 68; Davey and Williams, 1966b, p. 55.

Hystrichosphaeridium cf. arundum Eisenack and Cookson, 1960 (Plate 4, Fig. 12)

Remarks. The single specimen from the sample 547B-5-2, 47-50 cm is characterized by elongate, buccinate appendages that abruptly widen distally to funnels having twice the diameter of the process. In this process morphology, the cyst differs from the tubiferous appendages of a typical *Hystrichosphaeridium arundum* Eisenack and Cookson. The processes of *H*. cf. *arundum* with a length of 0.5 cyst diameter are significantly longer than the processes of *H*. *arundum*, with a length of 0.25 of a cyst diameter.

Occurrence. See Figure 3, No. 74: Sample 547B-5-2, 47-50 cm; late Albian.

Genus MAGHREBINIA Below, 1981

Type species. Maghrebinia perforata (Clarke and Verdier 1967) Below, 1981.

Diagnosis. Below, 1981, p. 22.

Maghrebinia perforata (Clarke and Verdier, 1967) Below 1981 ssp. mirabilis n. ssp. (Plate 6, Fig. 2)

Derivatio nominis. Latin mirabilis, beautiful.

Diagnosis. Chorate, somewhat lenticular cyst with bitrapezoidal size. Divided into a small epicyst and a greater hypocyst by an equatorial planispiral intratabular membrane. Paraplates bordered by high, distally denticulated, perforated or unperforated membranes, which are often irregularly and deeply slit. An apical area with few intratabular processes as well as the antapical, four precingular, and three postcingular paraplates are bordered by these septa. Nevertheless, the paraplate scheme could be 3'-?4', 5'', Oc, 4''', 1'''' because the large ventral area between polar plates is undifferentiated. The right end of the paracingulum extends into this area. The cyst surface is microfrangate (see Below, 1981, p. 23). Endophragmal gonal membranal thickening is often perforated. Archeopyle type \overline{A} .

Holotype. The specimen shown as *Maghrebinia perforata* (Clarke and Verdier, 1967) Below, 1981 in Plate 1, Figs. 1a, 1b, 1c, in Below 1981; slide VIII-4744 1/8.

Type locality. Section Ida ou Tanane in the north of Agadir, Morocco, section-meter 152.

Type level. basal Cenomanian.

Dimensions. Holotype: length 80 μ m; paratypes: length 62–96 μ m, breadth 60–90 μ m.

Remarks. The subspecies *Maghrebinia perforata* (Clarke and Verdier, 1967) Below, 1981 ssp. *mirabilis* n.ssp. differs from *M. perforata* (Clarke and Verdier, 1967) Below, 1981 ssp. *perforata* by its coarse and deep, irregular splitting of the high parasutural membranes. Septures of the letter subspecies are lower, are nearly constant in height, and are finely distally denticulated.

Two types of parasutural septa variations are now known: (1) the successive reduction of membrane height from *M. perforata* ssp. *mirabilis* to *M. perforata* ssp. *perforata*; (2) the second type is the interruption of membranes by deep splits and consequently the total absence of membranes between gonal thickenings, as occurs in the range of variation between *M. perforata* ssp. *mirabilis* and *M. chleuh* Below, 1981.

Occurrence. See Figure 1, No. 140: Sample 545-39-4, 94–97 cm to Sample 545-31-1, 130–133 cm, late Albian, basal and early Cenomanian; Figure 3, No. 32: Sample 549B-5-6, 50–53 cm to Sample 549B-2-2, 0–2 cm, late Albian; Figure 4, No. 9, Sample 549A-73-1, 148–150 cm to Sample 547A-48-2, 75–77 cm, late Albian to basal Cenomanian.

Genus OCCISUCYSTA Gitmez, 1970

Type species. Occisucysta balios Gitmez, 1970. Junior synonym. Diacanthum Habib, 1972. Diagnosis. Gitmez 1970, p. 267.

Occisucysta hinzii n.sp. (Plate 6, Figs. 7, 8; text, Fig. 6)

Derivatio nominis. In honor of Dr. Karl Hinz, Co-Chief Scientist of Leg 79.

Diagnosis. Large, proximate, two-layered, cornucavate, oval cyst with broad, pyramidal apical horn. Periphragma irregularly thickened to alveolate or forming a reticulum with muri and soli of variable width and shape. Very sparsely granulated. Endophragma thin, finely perforated. Paratabulation goniaulacacean ?PR, 4', 6'', Xc, as, ra, ls, rs, pv, 6''', 1''''. Parasutures marked by low, thick ridges that can expand to low septa. The hypocyst is distorted against the epicystal plate series so that 3''/4''' parasuture is mid-dorsal. Intratabular pseudosutures occasionally present. Archeopyle $2P_{2'',3''}$

Holotype. Slide IV 6938: 41.4/101.

Type locality. DSDP Leg 79, 545-45-4, 40-43 cm, Mazagan Plateau, off Northwest Africa.

Type level. late Aptian.

Dimensions. Holotype: length 78 μ m, breadth 67 μ m, length of endocyst 60 μ m, height of septa up to 3 μ m; other specimens: length 72-104 μ m, length of endocyst 60-86 μ m, width 60-84 μ m, height of septa up to 4 μ m.

Description. The large, two-layered cyst has a basically oval ambitus with an obvious, broad-based, hollow, equilateral pyramidal apical horn, which is positioned slightly off the anterior cyst pole and displaced in ventral direction (Plate 6, Fig. 8). The two cyst wall layers are closely attached, except at the apex where the outer layer forms the cornucavate apical protuberance. The periphragma is irregularly thickened and so gives rises to uneven, broad and high muri around soli of variable size and form (Fig. 6). Under light microscopy, the cyst wall appears alveolate. A few specimens show special thickenings of the muri to small intraparatabular pseudosutures, as described for Occisucysta brixii Below (1982a), or thickenings of intrabular areas as shown for Occisucysta evittii (Dodekova, 1969) Gitmez, 1970 by Below (1982a). General reduction of periphragmal structures is possible. Occasional specimens show nodes and tubercles as relicts of muri on a smooth or finely reticulated periphragma. The endophragma is smooth to finely reticulated. The cyst wall has low, thick parasutural ridges or-on a few

Figure 6. Occisucysta hinzii n.sp. detail of cystwall; E,p = perforated endophragma; P,s = solid periphragma; g = granulae; m = muri; s = solum.

specimens-narrow, perforated parasutural septa that are best developed around the antapex. The paratabulation is typically goniaulacacean. Preapical paraplates cannot be observed with absolute assurance, but there are faint lines on the apical horn that imply the existence of a top preapical 1PR and a second 2PR on the dorsal side of the horn. Four apical paraplates can be distinguished, a small, long 1', pentagonal 2' and 3' and the rhombic 4' that fills the angle be-tween 5'' and 6''. The precingular series are trapezoidal or pentagonal and of equal size, except for the smaller 6' '. The equatorially situated paracingulum is offset by its width at the parasulcus with its first and last paraplate bent posteriorly. The postcingular series begins with a small rectangular 1'''. This is poorly separated from the parasulcus by a parasutural rib, but differs by its alveolate texture from the smooth ls. The postcingular series continues with the equilaterally triangular 2''' and the trapezoidal 3''' to 6'''. The pv paraplate is very elongated and poorly defined against pr, ps, and ls, because of the absence of parasutural ridges. In the parasulcus it is possible to distinguish the elongated smooth ls, a long rs and an arrowshaped ps that is bent into a small antapical 1''''. Paraplate series of epicyst and hypocyst are distorted as in Cribroperidinium (Gocht, 1979; Below, 1981), so that the 3'''/4''' boundary is mid-dorsal. The archeopyle-type is $2P_{2''-3''}$, but in some specimens paraplate 1'' and/ or 4'' are lost also.

Comparison. The irregularly thickened cyst wall with various shapes of muri and soli is unique among species of the genus *Occisucysta*.

Occurrence. see Figure 1, No. 99: Sample 545-49-5, 49-52 cm to Sample 545-44-2, 78-82 cm; middle to late Aptian.

Occisucysta mazaganensis n.sp. (Plate 6, Fig. 9; Plate 7, Fig. 1; text, Fig. 7)

Derivatio nominis. Mazagan, town in Morocco. DSDP Leg 79 Sites are situated near submarine Mazagan Plateau.

Diagnosis. Large, proximate, spheroidal, two-layered, acavate or cornucavate cyst with a low apical bulge. Endophragma smooth, periphragma reticulated, bearing solid, irregularly interconnected spines that are strung together on parasutures. Paratabulation goniaulacacean ?XPR, 4', 6'', Xc, as, rs, ls, ps, pv, 6''', 1'''', with torsion of hypocyst against epicyst so that the 3'''/4''' paraplate boundary is mid-dorsal. One or two additional, isolated, solid spines per paraplate. Archeopyle type $2P_{2'',3''}$.

Holotype. Slide III-6879: 40.6/107.7.

Type locality. DSDP Leg 79, 547B-5-5, 100-103 cm; Mazagan Plateau, off Northwest Africa.

Type level. late Albian.

Dimensions. Holotype: length 86 μ m, breadth 72 μ m, length of spines 6 μ m to 10 μ m; other specimens: length 78-95 μ m, breadth 68-81 μ m, length of spines 2-12 μ m.

Description. The large, two-layered cyst has an overall oval to subspheroidal ambitus. It tapers apically, forming an apical horn or a low, apical bulge. The smooth endophragma and the reticulated peri-

Figure 7. Occisucysta mazaganensis n.sp., detail of cystwall; E,s = solid endophragma; P,p = perforated periphragma; pS = parasutural spine row.

phragma are attached. Only in a few cases do they form a cornucavate pericoel in the apical region. The cyst wall gives rise to solid acuminate spines of varying height and width, which are arranged on parasutures. Spines are irregularly connected at different heights (Fig. 7). Generally, there are one or two solid, acuminate intratabular spines in the center of most paraplates. A goniaulacacean paratabulation is defined: ?XPR, 4', 6'', Xc, as, rs, ls, ps, pv, 6''', 1''''. The preapical plates are difficult to distinguish because the apical horn builds a complicated trestle, formed by the junctions of the parasutural spine-rows between apical paraplates. Nevertheless, the crownlike morphology of the apical horn tip implies the existence of such preapical paraplates. The apical series is comprised of a narrow, long 1', pentagonal 2' and 3' and a rhombic 4'. Paraplate 4' fills the angle between 5'' and 6' as is typical for the species of the genus Occisucysta. The paraplates of the precingular series are trapezoidal or pentagonal and equally large, except for the smaller pentagonal 6' '. The equatorially situated paracingulum is offset by its width at the parasulcus. In contrast to other paraplates, the paracingulum bottom is built up of a very coarse periphragmal net. The postcingular series begins with a small rectangular 1''' and continues with the equilateral triangular 2''' and trapezoidal 3''' to 6'''. The pv plate is elongate and polygonal. In the parasulcus, it is possible to observe the anterior/posteriorly elongated rs and ls and an arched ps. The trapezoidal 1'''' is indented by this ps paraplate. Epicyst and hypocyst series are distorted so that the 1/4''' boundary is mid-dorsal. Archeopyle type $2P_{2'',3'}$

Comparison. The irregularly connected rows of parasutural spines, which look like a crown of thorns, are typical for this species, which resembles only *Occisucysta paucispina* (Eisenack and Cookson, 1960) Below, 1981. This species has few parasutural spines which are not connected or are only basally interconnected.

Occurrence. See Figure 1, No. 143: Sample 545-39-1, 93-96 cm, late Albian; Figure 3, No. 33: Sample 547B-5-6, 50-53 cm to Sample 547B-2-2, 0-2 cm, late Albian.

Genus OLIGOSPHAERIDIUM Davey and Williams, 1966

Type species. Oligosphaeridium complex (White, 1842) Davey and Williams 1966.

Diagnosis. Davey and Williams, 1966b, p. 70.

Oligosphaeridium verrucosum Davey, 1979 (Plate 7, Figs. 11, 12, 13)

Remarks. Oligosphaeridium verrucosum, a very large species, tends to show a greater degree of variability in cyst wall ornamentation than other species of the genus Oligosphaeridium. Within the

same population one can observe specimens with either dense or sparse distribution of large granulae; or individuals with a very dense but fine granulation; or specimens with a scabrate or smooth cyst wall. **Occurrence.** See Figure 1, No. 80: Sample 545-52-2, 123-126 cm to Sample 545-47-6, 72-75 cm; middle to late Aptian.

Genus SPINIFERITES Mantell, 1850, emend. Sarjeant, 1970

Type species. Spiniferites ramosus (Ehrenberg, 1838) Loeblich and Loeblich, 1966.

Diagnosis. Mantell, 1850, p. 191: Sarjeant, 1970, p. 75.

Spiniferites cf. wetzelii (Deflandre, 1937) Sarjeant, 1970 (Plate 9, Fig. 15)

Remarks. This species is characterized by high parasutural septa between the gonal processes. These processes are only slightly higher than the parasutural membranes and are distally bifurcated or trifurcated. In contrast to the typical *Spiniferites wetzelii* with distally smooth septa, the membranes of the species discussed here have broad but bifurcate appendages.

Occurrence. See Figure 1, No. 89: Sample 545-51-1, 47-50 cm, middle Aptian; Figure 3, No. 46: Sample 547B-5-5, 100-103 cm to Sample 547B-5-1, 0-3 cm, late Albian.

Genus SYSTEMATOPHORA Klement, 1960

Type species. Systematophora areolata Klement, 1960. Diagnosis. Klement, 1960, p. 61.

Systematophora? sp. MAZ (Plate 10, Fig. 2: text, Fig. 8)

Description. Spheroidal, two-layered chorate cyst. Endophragma smooth, periphragma finely fibrous, especially where forming processes. Processes of one individual are all of equal length—corresponding to half the cyst body diameter but of somewhat unequal diameter. The processes are hollow and are either tubiform or distally somewhat widened. The process wall is made up of very fine fibers which are irregularly connected to a fine-meshed net. The distal process margins are deeply split. A few thin, simple, solid appendages are present. The arrangement of processes is unknown and reconstruction of paratabulation is therefore impossible. Archeopyle unknown.

Remarks. There are too few well preserved and favorably oriented specimens to formally erect a new species. Nevertheless, this striking cyst is a typical component of some Aptian and Cenomanian dinoflagellate cyst assemblages.

Figure 8. Systematophora? sp. MAZ, fibrous processes of variable morphology.

Occurrence: See Figure 1, No. 91: Sample 545-50-6, 56-58 cm to Sample 545-33-1, 90-94 cm, middle and late Aptian, basal Cenomanian; Figure 4, No. 63: Sample 547-63-2, 0-2 cm, basal Cenomanian.

ACKNOWLEDGMENTS

I wish to acknowledge Prof. H. K. Erben and Prof. K. J. Müller, directors of the Institut für Paläontologie, Rheinische Friedrich-Wilhelms Universität Bonn, who made working facilities and material available to me. Acids used in the palynological preparation were donated by BAYER AG, Leverkusen.

I would also express my thanks to Dr. H. Gocht, Tübingen, and Dr. J. Jansonius, Calgary, for critically reading the manuscripts and to Mrs. B. Martin, Bonn, for revising the English.

Financial support was given by the Heinrich-Hörlein-Stiftung of the Fachgruppe Erdwissenschaften, Rheinische Feridrich-Wilhelms Universität Bonn.

Date of Initial Receipt: November 23, 1982 Date of Acceptance: July 6, 1983

Plate 1. (Scale bar = 10 μm.) 1. Achomosphaera ramulifera, length 66 μm, oblique cingular view; slide II-6909: 22.1/98, Sample 547A-63-4, 46-48 cm.
2. Achomosphaera sagena, length 70 μm, oblique cingular view with different focus; slide II-6889: 30.9/108.1, Sample 547A-63-4, 75-77 cm.
3. Achomosphaera triangulata, length 72 μm, oblique cingular view; slide II-6898: 45/105.4; Sample 547A-56-2, 48-51 cm.
4. Achomosphaera verdieri, length 56 μm, oblique cingular view; slide I-6954: 32.7/99.2; Sample 545-55-1, 60-62 cm.
5-7. Aptea almohadensis n.sp., (5) breadth 70 μm, holotype; dorso-ventral orientation, (A, circular focus; B, ventral focus), slide II-9646: 49.6/100.4, Sample 545-49-5, 49-52 cm; (6) breadth 75 μm; specimen with few and very low ornaments; slide III-6944: 29.2/99.3, Sample 545-48-6, 16-18 cm; (7) breadth of operculum 45 μm; operculum consists of four apical paraplates; slide II-6946: 40.8/103,3, Sample 545-49-5, 49-52 cm.
8-9. Aptea eisenackii, (8) breadth 77 μm, ventral focus, slide I-6951: 45/109.6, Sample 545-52-2, 123-126 cm; (9) breadth operculum 45 μm, apical view; note splits along parasutures between the four apical paraplates, slide II-6944: 47.5/104.4, Sample 545-48-6, 16-18 cm.
10. Aptea polymorpha, length 96 μm, dorsal focus, slide I-6955: 54.9/106.4, Sample 545-59-6, 71-73 cm.
11. Apteodinium maculatum, length 72 μm, oblique view, slide I-6938: 27/105.2, Sample 545-45-4, 40-43 cm.
12. Batiacasphaera saidensis, breadth 60 μm, operculum inside the vesicle, ventral focus, slide I-6951: 40.3/113.5, Sample 545-45-4, 40-43 cm.
13-14. Carpodinium granulatum, (13) length 60 μm, ventral focus, slide III-6946: 43.8/103.2, Sample 545-47-6, 72-75 cm.

Plate 2. (Scale bar = 10 μm.) 1. Cassiculosphaeridia reticulata, breadth 65 μm, focused on reticulated surface ornamentation, slide I-6915: 41.9/112.2, Sample 547A-71-2, 83-85 cm.
2. Cerbia tabulata breadth 74 μm, specimen with low ornaments, (A) ventral focus, (B) dorsal focus; slide I-6937: 27.5/96.9; Sample 545-45-1, 59-62 cm.
3. Cleistosphaeridium clavulum, diameter 54 μm; slide III-6891: 37.5/105.7, Sample 547A-50-2, 130-133 cm.
4. Cleistosphaeridium multispinosum, diameter 77 μm, cingular view; slide III-6878: 47/106.2, Sample 547A-51-4, 0-2 cm.
5. Codoniella campanula, length 96 μm, dorsal view, focused on precingular archeopyle, slide III-6893: 35.7/94.8, Sample 547A-51-4, 0-2 cm.
6. Codoniella psygma, (6) length 74 μm, dorsal focus, slide I-6937: 36.9/98.3, Sample 545-45-1, 59-62 cm, (7) length 84 μm, ventral focus, slide III-6930: 33.2/93,4, Sample 545-40-6, 57-60 cm.
8. Cometodinium? whitei, diameter 76 μm, slide I-6952: 45.5/94, Sample 545-53-3, 90-94 cm.
9. Coronifera oceanica, length 84 μm, cingular view, slide II-6895: 42.6/98, Sample 547-45-31, 100-103 cm.
10. Coronifera tubulosa, length 105 μm, dorsal precingular archeopyle showing to left top of figure, slide II-6938: 32.3/94.7, Sample 545-45-4, 40-43 cm.
11. Cribroperidinium orthoceras, length 120 μm, ventral focus, slide II-6946: 36.8/104, Sample 545-49-5, 49-52 cm.
12. Cyclonephelium brevispinatum, diameter 80 μm, ventral focus, slide III-6946: 36.8/104, Sample 545-49-5, 49-52 cm.
13. Cyclonephelium chabaca, breadth 81 μm, dorso-ventral orientation, (A) cingular focus, slide II-6878: 30.3/108.5, Sample 547B-5-4, 147-150 cm.
14. Cyclonephelium compactum, breadth 78 μm, ventral focus, slide III-6878: 30.3/108.5, Sample 547B-5-4, 147-150 cm.

Plate 3. (Scale bar = 10 μm.) 1. Cyclonephelium compactum, length 90 μm, ventral focus, slide I-6878: 49.6/104.1, Sample 547B-5-4, 147-150 cm. 2. Cyclonephelium distinctum, (2) breadth 96 μm, cingular focus, slide II-6924: 42.3/101.1, Sample 545-36-1,44-47 cm. (3) breadth 78 μm, note operculum splits between the four apical paraplates, 1' to the south, slide III-6919: 41.6/99.3, Sample 545-31-1, 130-133 cm. 4. Cyclonephelium hystrix, breadth 66 μm, dorsal focus; slide II-6938: 32.2/110.1, Sample 545-45-4, 40-43 cm. 5. Cyclonephelium maugaad, breadth 70 μm, ventral focus, slide III-695: 49.7/108.6, Sample 545-49-1, 34-37 cm. 6. Cyclonephelium cmbraniphorum, diameter 78 μm, cingular focus, slide III-6869: 27.6/108.1, Sample 547B-22, 0-2 cm. 7. Cyclonephelium paucimarginatum diameter 78 μm, cingular view, slide III-6905: 27/106, Sample 547A-61-2, 0-2 cm. 8. Dingodinium albertii, length 57 μm, slide I-6941: 37.8/93.5, Sample 545-47-2, 97-99 cm. 9-11. Dissiliodinium globulum, (a) length 102 μm, note apical paraplates, slide II-6938: 31.6/113.4, Sample 545-45-4, 40-43 cm; (10) breadth 66 μm, note four apical paraplates and preapical structures, slide I-6942: 40.7/111.7, Sample 545-47-6, 72-75 cm; (11) diameter 60 μm, apical focus, slide I-6942: 30.7/108.2, Sample 545-47-6, 72-75 cm. 12. Ellipsoidictyum imperfectum length 54 μm, ventral focus, slide II-6942: 45/111,9, Sample 545-47-6, 72-75 cm. 13. Epelidosphaeridia spinosa, breadth 48 μm, (A) surface focus, (B) cingular focus, slide I-6919: 32.5/101.6; Sample 545-47-6, rac-75 cm. 14. Exochosphaeridium bifidum, length 90 μm, dorso-ventral orientation, operculum of precingular archeopyle somewhat distorted, cingular focus, slide II-6942: 47/104.1; Sample 545-48-6, 16-18 cm. 15. Eyrea nebulosa, diameter of central body 38 μm, note small apical bulge to the north, slide II-6987: 29/111.4, Sample 547-45-52, 69-71 cm.

Plate 4. (Scale bar = 10 μm.) 1. Florentinia laciniata ssp. laciniata, length 95 μm, dorso-ventral orientation, (A) ventral focus, (B) cingular focus, (C) dorsal focus demonstrating the combination archeopyle, formed by loss of apical paraplates and the third precingular paraplate, slide II-6901: 32.4/94.8, Sample 547A-59-2, 0-2 cm. 2. Florentinia mantellii, length 78 μm, (A, B) two different foci, slide III-6896: 47.8/94.6, Sample 547A-54-1, 60-62 cm. 3. Florentinia radiculata, length 72 μm, oblique cingular view, slide II-6870: 46.2/106.4, Sample 547B-2-4, 116-120 cm. 4. Florentinia resex, length 84 μm, oblique cingular view, slide II-6914: 44/103.7, Sample 547A-70-2, 90-93 cm. 5. Florentinia stellata, length 84 μm, oblique cingular view, slide II-6916: 38.3/95.6, Sample 547A-61-4, 113-115 cm. 6. Fromea amphora, length 58 μm, slide II-6946: 44.1/98.6, Sample 545-49-5, 49-52 cm. 7. Gonyaulacysta cretacea, length 48 μm, oblique cingular view, dorsal to the left, slide III-6946: 44.1/98.6, Sample 545-48-6, 16-18 cm. 8. Gonyaulacysta helicoidea, length 58 μm, ventral focus, slide 6879: 26.1/111.3, Sample 547A-63-4, 46-48 cm. 10. Hapsocysta dictyota, diameter 66 μm, oblique cingular view, slide II-6878: 42.8/104, Sample 547B-5-4, 147-150 cm. 11. Hystrichosphaeridium arundum, diameter 36 μm, oblique view, slide II-6872: 30.3/105.1, Sample 547B-5-1, 0-3 cm. 12. Hystrichosphaeridium cf. arundum, diameter 46 μm, note the long processes and compare with the typical H. arundum (Fig. 11), slide I-6874: 32.3/101.4, Sample 547B-5-2, 47-50 cm. 13. Hystrichosphaeridium atlasense, diameter 75 μm, apical focus, slide III-6873: 45.9/109.8, Sample 547B-5-1, 102-105 cm.

Plate 5. (Scale bar = 10 μm.) 1. Hystrichosphaeridium bowerbankii, length 72 μm, (A) ?dorsal focus, (B) oblique view, slide III-6919: 37.2/ 101.1, Sample 545-31-1, 130-133 cm. 2-4. Kiokansium corollum (2) length 88 μm, (A) oblique surface focus, (B) oblique cingular focus, archeopyle to the right, slide I-6922: 27.8/111.5, Sample 545-34-3, 44-46 cm; (3) length 86 μm, oblique cingular focus, archeopyle to the left, note extremely elongated form, slide II-6915: 43.8/105.7, Sample 547A-71-2, 83-85 cm; (4) length 60 μm, note the extreme reduction of appendages, slide II-6895: 43.5/99.4, Sample 547A-53-1 100-103 cm. 5. Kiokansium hydra, length 63 μm, oblique cingular view, archeopyle to the left, slide I-6946: 34.4/107.5, Sample 545-49-5, 49-52 cm. 6. Kiokansium polypes, diameter 68 μm, oblique cingular focus, slide I-6941: 45.6/105.2, Sample 545-47-2, 97-99 cm. 7. Kleithriasphaeridium eoinodes, length 75 μm, oblique cingular focus, archeopyle to the left, slide I-6936: 31.4/97.1, Sample 545-44-2, 78-82 cm. 9. Litosphaeridium conispinum, diameter 60 μm, (A) ventral focus, (B) oblique surface focus, slide II-6880: 49.8/109.3, Sample 547B-5-6, 50-53 cm. 10-11. Litosphaeridium siphoniphorum, (10) length 68 μm, ventral focus, slide II-6893: 33.7/111.3, Sample 547A-51-4, 0-2 cm.

Plate 6. (Scale bar = 10 μm.) 1. Maghrebinia chleuh, length 72 μm, oblique cingular view, slide II-6901: 51.3/106.3, Sample 547A-59-2, 0-2 cm. 2. Maghrebinia perforata ssp. mirabilis n.ssp., length 78 μm, slide III-6919: 30.6/108.7, Sample 545-31-1, 130-133 cm; 3. Maghrebinia perforata ssp. perforata, length 78 μm, (A, dorsal focus; B, ventral focus), slide III-6889: 35.7/97.5, Sample 547A-48-2, 75-77 cm. 4. Meiourogonyaulax cf. bulloidea, diameter 72 μm, (A) apical focus, (B) antapical focus, slide IV-6938: 41.4/101, Sample 545-45-4, 40-43 cm. 5-6. Muderongia perforata, (5) length 84 μm, dorsal focus, slide III-6936: 31.6/111.2, Sample 545-44-2, 78-82 cm; (6) breadth of operculum, 40 μm, slide III-6947: 39/106.5, Sample 545-50-1, 147-150 cm. 7-8. Occisucysta hinzii n.sp., length 96 μm, holotype (A, dorsal focus; B, cingular focus, C, ventral focus); slide IV-6938: 41.4/101, Sample 545-45-4, 40-43 cm; (8) length 102 μm, (A oblique view, note surface structure; B, oblique cingular focus, note apical horn in somewhat excentrical positions) slide 1-6937: 48.4/105.6, Sample 545-45-1, 59-62 cm. 9. Occisucysta mazaganensis n.sp., length 96 μm, (A) ventral focus, (B) cingular focus, (C) oblique dorsal focus, slide I-6879: 31.2/106,8, Sample 547B-5-5, 100-103 cm.

Plate 7. (Scale bar = 10 μm.) 1. Occisucysta mazaganensis n.sp., length 84 μm, holotype, (A) ventral focus, (B) dorsal focus, slide III-6879: 40.7/ 107.7, Sample 547B-5-5, 100-103 cm.
2. Occisucysta sousensis, length 72 μm, (A) dorsal focus, (B) ventral focus, slide II-6930: 43.1/99.8, Sample 545-40-6, 57-60 cm.
3. Odontochitina operculata, length 265 μm, dorsal focus, slide II-6905: 36.6/110, Sample 547A-61-2, 0-2 cm.
4. Oligosphaeridium asterigerum, diameter 72 μm, focused on distal termination of processes, slide III-6873: 41/110.8, Sample 547B-5-1, 102-105 cm.
5. Oligosphaeridium complex, diameter 90 μm, ventral focus, slide I-6954: 41.3/107.3, Sample 545-55-1, 60-62 cm.
6. Oligosphaeridium dividuum, diameter 108 μm, slide II-6897: 35.7/112.5, Sample 547A-55-2, 69-71 cm.
7. Oligosphaeridium cf. albertense, slide III-6939: 36/102.7, Sample 545-46-2, 63-66 cm.
8. Oligosphaeridium poculum, diameter 70 μm, dorsal focus, slide III-6909: 24.4/100.8, Sample 547A-63-4, 46-48 cm.
10. Oligosphaeridium totum ssp. minor, diameter 102 μm, cingular focus, slide II-6948: 32.5/105.2, Sample 545-50-6, 56-58 cm;
11-13. Oligosphaeridium verrucosum, (11) diameter 114 μm, note coarse granulae, slide I-6945: 30.2/105, Sample 545-49-1, 34-37 cm; (12) diameter 114 μm, note dense granulation, slide III-6950: 42/100.2, Sample 545-51-6, 66-69 cm; (13) diameter 86μm, note the smooth surface, slide I-6944: 39/107.8, Sample 545-48-6, 16-18 cm.

APTIAN TO CENOMANIAN DINOFLAGELLATE CYSTS, MAZAGAN PLATEAU

Plate 8. (Scale bar = 10 μm.) 1-2. Oodnadattia alata, (1) diameter 96 μm, apical view, slide I-6919: 38.2/109, Sample 545-31-1, 130-133 cm; (2) length 84 μm, dorsal focus, slide I-6919: 29.6/103.4, Sample 545-31-1, 130-133 cm. 3-4. Oodnadattia tuberculata, (3) diameter 72 μm, antapical view, slide I-6893: 36/106.4, Sample 547A-51-4, 0-2 cm; (4) diameter 78 μm, dorsal focus, slide II-6909: 23,4/106.4, Sample 547A-59-4, 148-150 cm. 5. Ovoidinium diversum?, diameter 48 μm, cingular focus, slide III-6869: 43.5/101.5, Sample 547B-2-2, 0-2 cm. 6. Ovoidinium implanum?, diameter 48 μm, slide I-6896: 45.9/109.9, Sample 547A-54-1, 60-62 cm. 7. Ovoidinium scabrosum, (7) breadth 48 μm, dorsal focus, slide III-6896: 38.8/102, Sample 547-54-1, 60-62 cm. (8) breadth 48 μm, dorsal focus, slide III-6897: 25.6/104.4, Sample 547A-55-2, 69-71 cm. 9-10. Ovoidinium verrucosum, (9) length 66 μm, slide III-6895: 30.4/97.8, sample 547A-55-1, 100-103 cm; (10) breadth 51 μm, slide I-6922: 28.5/99, Sample 545-34-3, 44-46 cm. 11. Palaeohystrichophora infusorioides, length 60 μm, slide I-6926: 37/108.3, Sample 545-38-1, 120-123 cm. 12. Palaeoperidinium cf. cretaceum, length 78 μm, slide II-6897: 30.3/100.7, Sample 547A-55-2, 69-71 cm. 13. Pervosphaeridium pseudohystrichodinium, diameter 85 μm, oblique orientation, (A) cingular focus, (B) surface focus, archeopyle to the right, operculum in situ, slide II-6912: 48.9/96.9, sample 547A-68-1, 101-105 cm. 14. Pervosphaeridium truncatum, length 97 μm, oblique cingular focus, archeopyle to the left, slide II-6919: 49.8/105.5, Sample 545-31-1, 130-133 cm. 15. Polysphaeridium sp. sensu Below (1982b), diameter 54 μm, slide II-6937: 45.4/101.3, Sample 545-45-1, 59-62 cm.

Plate 10. (Scale bar = 10 μm.) 1. Subtilisphaera deformans, length 77 μm, ventral focus, slide II-6944: 47.8/107.4, Sample 545-48-6, 16-18 cm. 2. Systematophora? sp. MAZ, diameter 72 μm, note fibrous processes, slide I-6946: 48.3/113.2, Sample 545-49-5, 49-52 cm. 3-4. Systematophora cretacea (3) max. breadth of operculum 84 μm, operculum with three apical paraplates attached, one paraplate lost, slide III-6938: 32.7/98, Sample 545-45-4, 40-43 cm; (4) breadth 102 μm, dorsal focus, slide I-6938: 33.1/110.3, Sample 545-45-4, 40-43 cm. 5. Tanyosphaeridium boletum, length 48 μm, slide II-6922: 31.8/108, Sample 545-34-3, 44-46 cm. 6. Trabeculodinium quinquetrum, length 60 μm, slide I-6917: 32.8/97.5, Sample 547A-72-4, 147-150 cm. 7. Trichodinium castanea, diameter 60 μm, slide III-6915: 37.2/100.1, Sample 547A-71-2, 83-85 cm. 8. Wallodinium luna, length 70 μm, slide I-6937: 26.1/101, Sample 545-45-1, 59-62 cm. 9-12. Xenascus creatioides, length 114 μm, slide II-6905: 50/111.8, Sample 547A-63-4, 46-48 cm; (10) length 74 μm, slide II-6882: 46.8/102.3, Sample 547A-21-4, 110-113 cm; (11) length 96 μm, slide II-6904: 33.7/100, Sample 547A-60-4, 138-140 cm; (12) length 110 μm, slide II-6903: 36.5/104, Sample 547A-60-2, 0-2 cm; note high morphological variability of X. ceratioides shown in Figs. 9-12.
